

Our Milky Way Galaxy On Collision Course with Huge Gas Cloud - 40 Million Years from Now

© 2008 Linda Moulton Howe

"Smith's Cloud is eleven thousand light-years long, 2,500 light-years wide and is only 8,000 light-years from our Milky Way Galaxy's disk. It is moving toward our galaxy at more than 150 miles per second, aimed to strike at an angle of about 45 degrees."

January 12 , 2008 Austin, Texas - The National Radio Astronomy Observatory (NRAO) is a facility of the National Science Foundation, operated under cooperative agreement by Associated Universities, Inc. Its headquarters and technology center are in Charlottesville, Virginia which coordinate the research of the Green Bank Telescope (GBT) in West Virginia; the Very Large Array, Very Long Baseline Array and Expanded Very Large Array in Socorro, New Mexico; and two other instruments in Tucson, Arizona, and Santiago, Chile.

On Friday, January 11, 2008, NRAO released the following report at the American Astronomical Society meeting in Austin, Texas: "A giant cloud of hydrogen gas is speeding toward a collision with our Milky Way Galaxy, and when it hits -- in less than 40 million years -- it may set off a spectacular burst of stellar fireworks.

‘The leading edge of this cloud is already interacting with gas from our Galaxy,’ said Felix J. Lockman, of the National Radio Astronomy Observatory (NRAO), leader of a team of astronomers who used the National Science Foundation's Robert C. Byrd Green Bank Telescope (GBT) to study the object. The scientists presented their findings to the American Astronomical Society's meeting in Austin, Texas.

The cloud, called Smith's Cloud, after the astronomer who discovered it in 1963, contains enough hydrogen to make a million stars like the Sun. Smith's Cloud is eleven thousand light-years long, 2,500 light-years wide and is only 8,000 light-years from our Milky Way Galaxy's disk. It is moving toward our galaxy at more than 150 miles per second, aimed to strike at an angle of about 45 degrees.

‘This is most likely a gas cloud left over from the formation of the Milky Way or gas stripped from a neighbor galaxy. When it hits, it could set off a tremendous burst of star formation. Many of those stars will be very massive, rushing through their lives quickly and exploding as supernovae. Over a few million years, it'll look like a celestial New Year's celebration, with huge firecrackers going off in that region of the Galaxy,’ Lockman said.

When Smith's Cloud was first discovered, and for decades after, the available images did not have enough detail to show whether the cloud was part of the Milky Way, something being blown out of the Milky Way, or something falling in.

Lockman and his colleagues used the Green Bank Telescope to make an extremely detailed study of hydrogen in Smith's Cloud. Their observations included nearly 40,000 individual pointings of the giant telescope to cover the cloud with unprecedented sensitivity and resolution. Smith's Cloud is about 15 degrees long in the sky, 30 times the width of the full moon.

‘If you could see this cloud with your eyes, it would be a very impressive sight in the night sky,’ Lockman said. ‘From tip to tail it would cover almost as much sky as the Orion constellation. But as far as we know it is made *entirely* of gas -- no one has found a single star in it.’

The detailed GBT study dramatically changed the astronomers' understanding of the cloud. Its velocity shows that it is falling into the Milky Way, not leaving it, and the new data show that it is plowing up Milky Way gas before it as it falls.

‘Its shape, somewhat similar to that of a comet, indicates that it's already hitting gas in our

Galaxy's outskirts,' Lockman said. 'It is also feeling a tidal force from the gravity of the Milky Way and may be in the process of being torn apart. Our Galaxy will get a rain of gas from this cloud, and then in about 20 to 40 million years, the cloud's core will smash into the Milky Way's plane,' Lockman explained.

Smith's Cloud will likely strike a region somewhat farther from the Galactic center than our Solar System and about 90 degrees ahead of us in the Milky Way disk. The collision may trigger a period of rapid star formation fueled by the new gas and the shock from the collision. Some theories say that the ring of bright stars not far from our own Sun, called Gould's Belt, was created by just such a collision event." [See **Gould's Belt Survey.**]
