

Part 2: Morphing UFO Over Levittown, PA - Scientific Research

© 2008 by Linda Moulton Howe

“The red-brown color observed and photographed in the Levittown leaves implies that the June and July leaves, filled with green chlorophyll, were subjected to external radiation - presumably the beamed energy from the aerial craft - that provoked leaf production of the red, protective pigment anthocyanin usually associated with fall leaves, not summer growth.”

- Biophysicist W. C. Levengood

Summer privet leaves with abnormal red-brown discoloration associated normally with fall production of the pigment anthocyanin. Hypothesis is that unusual external energies associated with the Levittown aerial phenomenon provoked premature anthocyanin production. Image © 2008 by W. C. Levengood, Pinelandia Biophysical Lab.

Earthfiles, news category.

Left: “Boomerang” version of mysterious aerial object that morphed into **middle** pink-colored disc. **Right:** The pink disc then flashed three oval, white lights on its bottom surface and “little squares of light” dropped like snow onto apartment yard and privet bush. Half a dozen sightings April through July 2008, Levittown, Pennsylvania. Image and drawings by resident and eyewitness.

Privet bush about 15 feet high grows next to eyewitness's apartment back door in Levittown, Pennsylvania, where “little squares of light” first fell on June 12, 2008 - and two more times in

Return to **Part 1**

November 14, 2008 Grass Lake, Michigan - W. C. Levengood, a biophysicist who worked on his Ph.D. at the University of Michigan, has received several patents concerning seed development. His research work about evidence of spinning plasma vortices containing microwave and other energies affecting plants and grasses in the global crop circle phenomenon has been published in the prominent journal, *Physiologia Plantarum: An International Journal for Plant Biology*.

W. C. Levengood, Biophysicist, in his Grass Lake, Michigan, laboratory. Photograph © by Linda Moulton Howe.

I began working with him in the early 1990s to investigate the global phenomenon of crop formations. Now retired at his Grass Lake, Michigan, Pinelandia Biophysical Laboratory, biophysicist Levengood has analyzed thousands of plants from crop formations in his own curiosity about what unusual energies are interacting with the plants to produce some of the biochemical and biophysical changes he has confirmed. In his own words, he says that “a spinning plasma vortex with a microwave, electrical and complex low energy ion-electron pulses” have interacted with many formation plants he has studied.

He also asserts that the energy interaction that creates formations must occur rapidly, in a few seconds. Otherwise, he would find evidence of burning or charring from the microwave heating. But he does not find such damage, and the formation plants continue to live and grow until harvest.

When Robert Gardner, field investigator for Pennsylvania's Mutual UFO Network (MUFON) contacted me in July 2008 for scientific research help in the Levittown mystery of a morphing aerial craft that dispersed little squares of light into the air around the privet and silver maple tree, I called biophysicist Levengood. The fourth appearance of the morphing UFO and its second time to disperse the mysterious little light squares occurred around 4:10 AM on July 8, 2008.

Bob Gardner collected branch and leaf samples from the exposed side of the privet bush and nearest silver maple tree for a Fed Ex shipment, which arrived at biophysicist's Michigan lab on July 16, 2008.

Then the sixth appearance of the morphing UFO and its third time to disperse the mysterious little squares of light occurred between 1 AM and 4 AM on July 16, 2008. Bob gathered more samples after that exposure and that second shipment arrived in the Michigan lab on July 24, 2008. He received leaf and bud samples from the privet bush; leaf and bud samples from the silver maple tree about 65 feet from the privet bush; control leaf and bud samples from another silver maple tree at the creek about 75 feet from the affected silver maple tree. No other privet bush could be found in the apartment region that matched the one in the eyewitness's yard; thus, no privet control was shipped to biophysicist Levengood.

Lab Report by Biophysicist W. C. Levengood
September 13, 2008

In this laboratory the customary procedure when receiving fresh plant material, is to immediately start examinations. In this case, surprises started when the well packaged privet branches were removed from a gallon Ziploc container bag, placed on the lab bench and very carefully arranged for general examination. As the limbs were being pulled apart it was noticed that there was a pile of leaves below them. Two thoughts came to mind; one "that's very strange" and two "maybe they were knocked off in shipment." An immediate inspection of the Ziploc bag from which the limbs had just been removed, disclosed not one leaf in the bag! Furthermore, shaking the branches with many leaves still remaining, did not produce additional leaf dropping – in fact this limb shaking was repeated for five consecutive days after the initial leaf shedding and no additional leaves were shed.

What we have here is an extremely unusual situation. In the mid-summer days of June and July, the leaves on all plants in the Northern Hemisphere are producing plant

food from photosynthetic activity, which at this period of development is occurring at a maximum rate. Heavy leaf fall just does not occur in mid-summer. However, in late September and October, leaf fall takes place naturally, brought about by the process of abscission. As the green chlorophyll in leaves begins to break down during the fall season with its reduced light levels and lower temperatures, there is an increase in the level of a plant hormone known as abscisic acid.

The level of abscisic acid becomes particularly high in what is referred to as the abscission layer within the leaf pulvinus (thick region at the base of the leaf petiole) and after the abscisic acid reaches a certain concentration, these cells rupture and the leaf falls to the ground. Not all the leaves fall at once, which is contrary to what occurred in the Philadelphia tree samples. The 167 leaves that spontaneously abscised onto the lab bench were all small and immature, again a situation contrary to what occurs in the course of seasonal leaf development. This process of leaf fall is also related to the role that abscisic acid has in the control of leaf senescence. As a plant matures, the older leaves at the basipetal region or bottom of the plant, may begin to loose chlorophyll due to various factors such as less efficient production of photosynthetic products. To conserve energy, the main body of the plant directs abscisic acid to the leaf and it falls off. In the 167 leaves that abscised on the lab bench, all were healthy leaves undergoing optimal production of photosynthetic compounds.

Macroscopic and Microscopic Examinations of Leaves

A close inspection of the 167 abscised leaves revealed the presence of what at first appeared to be a reddish-brown stain on the upper surface of the leaf. In Fig.1 the leaves in the top photograph illustrate the color variations and the sharp lines of demarcation between the affected red-brown areas and the green, unaffected regions. The leaf on the left side of the upper row was totally exposed to the energy beams. The spotty nature of the energy beam effect may be seen in the bottom photo in Fig.1, where as shown in the upper row-right leaf, the energy beam produced a sharp line, at the end of which is a hole extending through the tissue. The left leaf in the bottom row has very small red-brown spots, one indicated by the arrow. Here, the beam energy was not of sufficient magnitude to punch a hole clear through the leaf.

Figure 1. Privet leaves from abscised group (dropped from branches).
Note variations in the abnormal red-brown patterns produced by beamed external energies associated with the Levittown phenomenon. These and all images
© 2008 by W. C. Levensgood, Pinelandia Biophysical Laboratory.

In Fig.2, the top photo shows a maple leaf that has been peppered by energy beams that produced sharp lines, holes and sections that were almost cut away. The three privet leaves at the bottom of Fig.2, provided the first clear evidence that the energy beams were altering biochemical pathways inside the leaf tissue. In a normal developing leaf the distribution of chlorophyll is uniform. However, it is quite apparent that the upper segment of all three privet leaves in Fig.2, have a lighter green color than the lower region. Between these two green areas is a band of red-brown coloration, the characteristics of which are typical of the naturally occurring, red pigment anthocyanin. This pigment will be discussed in more detail in a later section of this report. This lighter coloration in the upper segment of these leaves indicates that the energy beam produced a partial breakdown of leaf chlorophyll.

Figure 2. Upper photo shows a maple leaf covered with lesions produced by the Levittown beamed energy phenomenon. Lower photo shows that upper segment of all three leaves exhibit

a lighter color than the bottom portions. The band of red-brown indicates the production of the natural pigment anthocyanin, presumed to have been provoked by energies released in Levittown phenomenon.

The two photomicrographs in Fig.3 (40x magnification) show relatively large energy beam holes in privet bush leaves. The top photo depicts a cavity with a very sharp, rectangular outline, surrounded by a red-brown band of anthocyanin coloration. In the bottom photo in Fig.3, the energy beam has cut out a circular lesion in the leaf, leaving the central region hanging by just a few tissue fibers. Again, the anthocyanin coloration is obvious at the edges of the opening and in the central segment. It is important to note that there is still green tissue in the central cut-out segment. This clearly suggests that the energy doing the cutting was a very fine beam with laser like precision.

Figure 3. Both photomicrographs at 40x magnification are representative of the type of energy beam holes found in both the privet and maple leaves. The cutout region in the lower photo was held in place by only a few fibers.

One might argue that these holes are just insect damage, however, there are factors that clearly rule out insect activity, for example, one finds no evidence of egg casts, excrement or larval cocoon formation. The top photo in Fig.4 illustrates an insect produced hole in one of the privet leaves, and the bottom photo (both at 40x) an insect produced hole in a maple leaf taken from a tree (control) located about 20 yards from the Pinelandia laboratory. The scallop outline around the edges of the holes in Fig.4, are typical of those produced by chewing insects. In addition, it should be noted that the red-brown anthocyanin coloration is absent in these photomicrographs.

Figure 4. Upper photo shows insect-produced hole in a privet leaf and in lower photo an insect-produced hole in a silver maple leaf. Both holes show typical chew marks at the edges. In addition, note the absence of the red-brown pigment observed in all affected leaves.

Significance of Anthocyanin Pigment

One of the functions of the pigment anthocyanin, which is present in most all land plants, is to provide plants with protection from excessively high levels of external radiation. Under normal conditions, the red color of the pigment is masked by the green coloration produced by leaf chlorophyll. But anthocyanin is present during the entire growth season. In late fall when the green chlorophyll begins to break down, the anthocyanin color becomes apparent in the red, pink and purple leaves that fall from most deciduous trees.

The red-brown color observed and photographed in the Levittown leaves implies that the June and July leaves, filled with green chlorophyll, were subjected to external radiation, presumably the beamed energy from the aerial craft, that provoked leaf production of the red, protective pigment anthocyanin usually associated with fall leaves, not summer growth. If red and green paint are mixed, the outcome is a red-brown paint similar to the colors on the privet leaves in Figures 1 and 2. Further, if the healthy summer privet leaves show red-brown splotches of color, that suggests the beamed energy striking the upper and outer leaves of the privet and maple tree was considerably outside the normal range of radiant energy plants experience from the sun. It is significant that the leaves most exposed to the beamed energy and splotched with the red-brown color were exposed to the sky. Those outer leaves protected other leaves growing underneath them.

Continued in **Part 3:** More plant anomalies.
